Formed deep within the earth's mantle, serpentine rocks found their way to the surface over millennia. Unique flora have evolved on serpentine soils, especially adapted to survive severe hardships of drought, heavy metals, and nutrient stress. The Klamath-Siskiyou Mountains of northwest California and southwest Oregon are the largest serpentine area in North America.

A laterite is the type of thick, nutrient poor soil that forms in the rainforest. In tropical rainforests where it rains literally every day, laterite soils form (figure 8). In these hot, wet, tropical regions, intense chemical weathering strips the soils of their nutrients. There is practically no humus.

Forest soils are the foundation of the entire forest ecosystem and complex, long-term interactions between trees, soil animals, and the microbial community shape soils in ways that are very distinct from agricultural soils. The composition, structure, and processes in forest soils at any given time reflect current conditions, as well as the legacies of decades (and even millennia) of interactions that shape each forest soil.
